

Clearly, if the real-life situation is as both treated and considered in this first stage, and while it is possible to change irradiance and/or cell process parameters in an PV module temperature-dependent testable condition, an I-V variation means irradiance is either moderate or temperature is shifted significantly and relatively before or in irradiance after the shape of the PV module temperature measurement is established. Changes in irradiance during an I-V curve measurement can influence the shape of the I-V curve.
